## Long theoretical questions

## Instructions

- 1. You will receive in your envelope an English and native language version of the questions.
- 2. You have 5 hours to solve 15 short (tasks 1-15) and 3 long tasks.
- 3. You can use only the pen given on the desk.
- 4. The solutions of each task should be written on the answer sheets, starting each question on a new page. Only the answer sheets will be assessed.
- 5. You may use the blank sheets for additional working. These work sheets will not be assessed
- 6. At the top of each page you should put down your code and task number.
- 7. If solution exceeds one page, please number the pages for each task.
- 8. Draw a box around your final answer.
- 9. Numerical results should be given with appropriate number of significant digits with units.
- 10. You should use SI or units commonly used in astronomy. Points will be deducted if there is a lack of units or inappropriate number of significant digits.
- 11. At the end of test, all sheets of papers should be put into the envelope and left on the desk.
- 12. In your solution please write down each step and partial result.

## Long theoretical questions (max 30 points each)

- 1. A transit of duration 180 minutes was observed for a planet which orbits the star HD209458 with a period of 84 hours. The Doppler shift of absorption lines arising in the planet's atmosphere was also measured, corresponding to a difference in radial velocity of 30 km/s (with respect to observer) between the beginning and the end of the transit. Assuming a circular orbit exactly edge-on to the observer, find the approximate radius and mass of the star and the radius of the orbit of the planet.
- 2. Within the field of a galaxy cluster at a redshift of z = 0.500, a galaxy which looks like a normal elliptical is observed, with an apparent magnitude in the *B* filter  $m_{\rm B} = 20.40$  mag.

The luminosity distance corresponding to a redshift of z = 0.500 is  $d_L = 2754$  Mpc.

The spectral energy distribution (SED) of elliptical galaxies in the wavelength range 250 nm to 500 nm is adequately approximated by the formula:

 $L_{\lambda}(\lambda) \propto \lambda^4$ 

(i.e., the spectral density of the object's luminosity, known also as the monochromatic luminosity, is proportional to  $\lambda^4$ .)

- a) What is the absolute magnitude of this galaxy in the *B* filter ?
- b) Can it be a member of this cluster? (write YES or NO alongside your final calculation)

<u>Hints:</u> Try to establish a relation that describe the dependence of the spectral density of flux on distance for small wavelength interval. Normal elliptical galaxies have maximum absolute magnitude equal to -22 mag.

3. The planetarium program 'Guide' gives the following data for two solar mass stars:

Star	1	2
Right Ascension	14 <sup>h</sup> 29 <sup>m</sup> 44.95 <sup>s</sup>	14 <sup>h</sup> 39 <sup>m</sup> 39.39 <sup>s</sup>
Declination	-62° 40′ 46.14″	-60 50' 22.10"
Distance	1.2953 pc	1.3475 pc
Proper motion in R.A.	-3.776 arcsec / year	-3.600 arcsec / year
Proper motion in Dec.	0.95 arcsec / year	0.77 arcsec / year

Based on these data, determine whether these stars form a gravitationally bound system. Assume the stars are on the main sequence. Write YES of bound or NO if not bound alongside your final calculation.

Note: the proper motion in R.A. has been corrected for the declination of the stars.
